

ABSTRACT

This project aims to create a personalized fashion recommendation system for Android devices that leverages machine learning (ML), computer vision, and natural language processing (NLP) to enhance the user experience. The system detects user mood through an MCQ-based survey processed by ML algorithms. Based on mood data and user clothing preferences, the system recommends suitable outfits using NLP techniques. A virtual try-on feature powered by computer vision provides a realistic visualization of outfits, while an AI-driven chatbot offers personalized fashion advice. Continuous learning from user interactions improves the system's recommendations over time. The proposed architecture utilizes AWS cloud services, Flask-based APIs, and MySQL for robust backend support, ensuring efficient, real-time functionality and seamless user experience. This innovative solution demonstrates the potential of ML and computer vision in the personalized fashion domain, optimizing accuracy, engagement, and efficiency.
